

## Class

### Results

Results storage for a cell on a 1D random walk of length `iters`. Results are stored for a number (`maxRun`) walks of length `iters`.

## Fields

<b>posx</b>	<i>type: int[][]</i> cell x position in the grid for each walk and each step of each walk. So dimensions are <code>maxRun*iters</code> .
<b>d</b>	<i>type: int[]</i> d holds the distance travelled at the end of each walk.
<b>dsq</b>	<i>type: int[]</i> d squared is just d, squared.
<b>dCount</b>	<i>type: int[]</i> This array is the size of the (1D) grid and counts how many cells end at each grid point at the end of their walk, over the total <code>maxRun</code> walks.
<b>mind,maxd</b>	<i>type: int</i> This is the range of d.
<b>maxdCount</b>	<i>type: int</i> The maximum value in <code>dCount</code> which may be used to scale output or find the most probable location etc.
<b>cellStats</b>	<i>type: double[]</i> An array to hold some statistics about this group of walks.
<b>lineage</b>	<i>type: int</i> a cell identifier.
<b>firstx</b>	<i>type: int</i> The grid spot at the beginning of the walk. This gets set in <code>CASStatic (saveCA)</code> at the beginning of the walk.

## Constructors

### **Results(int maxRun,int iters,int lin,int gSize)**

This constructor sets up arrays of the correct size and sets the lineage.

## Methods

### **setrunStats(int runCount,int maxit)** *Returns void*

find the distance travelled in this walk. Also calculate `dsq` and increment `dCount` at this position.

### **calcStats(int runCount)** *Returns void*

calculate the average values etc for this group of walks.
